REMARKS ON A WORLD-WIDE INVENTORY OF AVIAN ANATOMICAL SPECIMENS

RICHARD L. Zusi,¹ D. Scott Wood,^{2,3} and Marion Anne Jenkinson⁴

'National Museum of Natural History, Washington, D.C. 20560 USA; ²The University of Oklahoma, Norman, Oklahoma 73019 USA; and ⁴Museum of Natural History, University of Kansas, Lawrence, Kansas 66045 USA

ABSTRACT.—The Committee on Collections of the American Ornithologists' Union is preparing for publication three composite inventories of anatomical collections of the world. One will cover the 45 largest skeleton collections; another, the collections of spirit specimens; and the third, smaller skeleton collections. The inventories will be useful for managing collections and for planning research. Analysis of these inventories shows that some families and orders are well represented in collections but have not been extensively studied; by contrast, many are poorly represented at the generic and specific levels. About a third of the species of birds of the world are not available as skeletons, and the same is true for spirit specimens. Continued collecting is needed to replace specimens that are dissected, to enlarge the series available for most species, to fill gaps that now prevent comparative studies in some families, to build useful research collections in various parts of the world, and to salvage important species in advance of habitat destruction. *Received 12 July 1982, accepted 2 August 1982*.

THE Committee on Collections of the American Ornithologists' Union has been active since its inception in publishing information about avian museum collections. Two such reports provided general narrative descriptions of 283 North American collections (Banks et al. 1973, Clench et al. 1976), and a similar project, expanded to world-wide coverage, is now under way. In addition, the committee is now compiling a composite inventory of avian anatomical specimens in collections throughout the world. The purposes of this article are to describe the anatomical inventory, provide a brief history of its development and projected plans for the future, summarize some of its data, and discuss the inventory in relation to collection management and research.

HISTORY

The idea of a composite inventory of avian anatomical specimens in North American collections began in 1974 with Mary H. Clench, who then chaired the AOU Committee on Collections. Before the project could be initiated, her energies were diverted to a study of major museum collections and their users for the Panel

on Systematics Collections of an NSF-AOU Workshop on a National Plan for Ornithology (King and Bock 1978). Separately, but as part of that panel's report, Zusi distributed a questionnaire to 66 North American museums concerning the nature, uses, and curatorial problems of skeleton and spirit collections. From this questionnaire we learned that virtually all of the 44 museum curators who responded were willing to provide lists of their anatomical collections. One of the recommendations of the report was that the AOU should publish a composite inventory of anatomical collections (Zusi 1978), and this project then became Zusi's main responsibility as a member of the AOU Committee on Collections.

Beginning in 1979, Zusi requested inventories from 66 curators of North American collections. Scott Wood became a member of the committee in 1980 and joined him in the inventory project. As the new head of the committee, Marion Jenkinson continued support for the project and played an increasingly active role in its consummation. Wood urged that the inventories be computerized, and he designed the necessary algorithms. Gary D. Schnell at the University of Oklahoma generously offered access to computer facilities and contributed personnel for both programming and data entry. He will continue to maintain

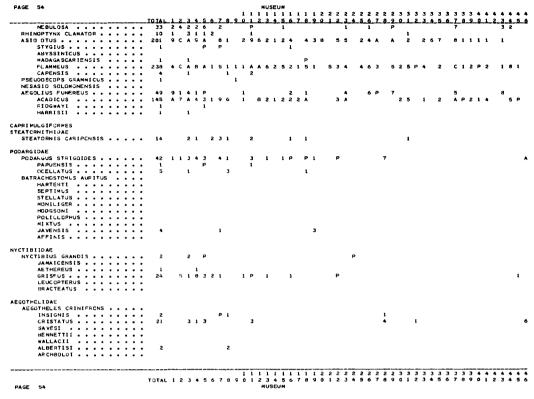

Fig. 1. Reduced photocopy of a sample page from the inventory of avian skeletal specimens. Columns are museum inventories. Letters represent holdings of different size classes (see text), and a blank space indicates the lack of a specimen.

and up-date the computer files. Although some inventories were compiled on coding forms by the curators of their respective collections, most were transcribed from the submitted inventories by Wood, Mary McKitrick, and Max C. Thompson.

Zusi determined the list of species of birds of the world to be used in the inventory, and Jenkinson entered the list onto tape. At her urging we also decided to include major museums from all parts of the world in the survey. Zusi then wrote to 45 curators in 24 countries, and, later, Wood, Jenkinson, and others wrote to additional museums. Curators were requested to submit separate inventories of skeletal and spirit specimens for each species in their collections. We have been much encouraged by the positive response from most curators. The first published inventories will include a minimum of 40 North American collections and 25 collections from other parts of the world.

Before the inventory project was initiated, Zusi (1978) recommended to the AOU that taxonomic and geographic guides to the anatomical specimens most critically needed should be prepared. The inventories, because they are in taxonomic order with all species of birds of the world listed, will provide an idea of the need for specimens at various taxonomic levels. In addition, the AOU has received a grant (DEB-8205935) from the National Science Foundation that will permit us to analyze the inventories from a geographic standpoint. That work is now under way, and the results should be published in about two years.

THE COMPOSITE INVENTORIES

Three kinds of composite inventories will be published separately as bound computer printouts (with citable titles and publication dates). Their titles will be: Inventory of avian skeletal specimens, 1982; Inventory of avian spirit specimens, 1982; and Supplementary inventory of avian skeletal specimens, 1982. The format for the first two is described below; that for the third will differ and be as condensed as possible.

Figure 1 shows a sample page from the inventory of larger skeleton collections. Each of the 46 numbered columns contains a museum inventory (in decreasing order of size from left to right). In the published version, column 46 will hold the totals from all museums in the inventory of smaller skeleton collections. Because each column except the first is only one character wide, all entries greater than 9 are represented by the following codes: A = 10-15; B = 16-25; C = 26-50; D = 51-100; E = 101-500; F = (>500). The first column, however, will give the actual total number of specimens for each species.

The systematic species list follows the nomenclature and arrangement of Morony et al. (1975), with a few minor changes and the following major exceptions: volume 1 (Mayr and Cottrell 1979) and volume 8 (Traylor 1979) of Peters' "Check-list of birds of the world" are followed, and new names have been added from Bock and Farrand (1980) and from card files in the National Museum of Natural History.

The numbers presented in the inventories represent, to our knowledge, complete specimens. Because of lack of time or assistance, however, some curators did not separate partial from complete skeletons, carcasses from complete spirit specimens, or chicks from adults in their specimen counts. Persons using these inventories to locate specimens for study should verify with the curator the precise nature of the specimens in question.

We shall add new data and new inventories to the computer files as they are received. When the changes in a composite inventory become significant, a new edition will be published. Instructions for ordering the composite inventories will appear in *The Auk, The Condor, The Wilson Bulletin, The Ornithological News Letter,* and in major ornithological journals throughout the world.

SUMMARY OF DATA

In comparison with skin collections, anatomical holdings are very small. The largest skin collections are approximately 35 times the size

of the largest skeleton collections, and in many museums the number is much higher. Table 1 summarizes the specimen holdings of the 36 largest skeleton collections for which we received inventories as of 1 June 1982, and Table 2 provides specimen totals for all of the spirit collections inventoried as of that date. We have also received 28 skeleton inventories from collections that either contain fewer than 1.000 skeletons each or, if larger, were received too late to be included in Table 1. These museums are (in alphabetical order): Acad. Nat. Sci. Philadelphia, Arch.-zool. Arbeitsgruppe (Schleswig), Australian Mus., Barbados Mus., Bolton Mus. (England), British Columbia Provincial Mus., Bulgarian Acad. Sci., Charleston Mus., Czechoslovakian Acad. Sci., Cleveland Mus. Nat. Hist., Forschungsinstitut Senckenberg (Frankfurt), Glasgow Mus., Koninklijk Mus. Midden-Afrika (Tervuren), Merseyside County Mus. (Liverpool), Midwestern State University (El Paso), Mus. Dierkunde (Gent), Mus. Nac. Hist. Nat. (Santo Domingo), Nat. Mus. Bulawayo, Polish Acad. Sci., St. Bonaventure Univ., Univ. Connecticut, Univ. Helsinki Zool. Mus., Univ. Montana, Univ. New Mexico, Univ. Texas El Paso, Uppsala Univ. Zool. Mus., Virginia Commonwealth Univ., Washington State Univ., Wayne State Univ. (Detroit).

In Table 3 the anatomical data are summarized by family and subfamily. The number of these families or subfamilies in which all genera or species are represented by skeletons or spirit specimens is high (71% for both skeletons and spirit specimens), but most of these are very small families or subfamilies containing fewer than 4 genera or 5 species. Families with more than 10 genera, all of which are represented by skeletons, are the Procellariidae, Threskiornithidae, Anatidae, Scolopacidae, Alcidae, Hirundinidae, and Mimidae; for spirit specimens they are the Procellariidae, Scolopacidae, Hirundinidae, Laniidae, Mimidae, Estrildidae, Ploceidae, and Corvidae.

Based on the inventories we have received, skeletons are apparently lacking only for the Oxyruncidae, Neodrepanidinae, and Hypocoliinae, and spirit specimens for Atrichornithidae. Only 1–5 skeletons have been reported for each of the following families or subfamilies: Pedionomidae, Dromadidae, Micropsittinae, Phodilinae, Brachypteraciidae, Philepittinae, Atrichornithidae, Pseudochelidoninae, Salpor-

nithinae, Rhabdornithidae, Catamblyrhynchinae, and Cnemophilinae. Apparently only 1–5 spirit specimens exist for the Casuariidae, Anseranatinae, Pedionomidae, Aramidae, Ibidorhynchidae, Strigopinae, Phodilinae, Leptosomatidae, Oxyruncidae, Neodrepanidinae, Hypocoliinae, Tichodromadinae, Salpornithinae, and Cnemophilinae. Table 3 reveals that some families and subfamilies for which anatomical specimens are available in large numbers are, nonetheless, poorly represented at the generic and specific levels.

Table 4 lists the number of species represented by a given number of specimens. Roughly a third of the species of birds of the world are not available as skeletons nor a similar fraction as spirit specimens. Many more

species that are available in collections are represented by 10 or fewer specimens than by more than 10 for both skeletons and spirit specimens.

The species best represented by skeletal specimens is the House Sparrow (Passer domesticus), with approximately 9,000. A few other species number between 1,000 and 3,000: Savannah Sparrow (Passerculus sandwichensis), Horned Lark (Eremophila alpestris), European Starling (Sturnus vulgaris), Dark-eyed Junco (Junco hyemalis), Ovenbird (Seiurus aurocapillus), Red-eyed Vireo (Vireo olivaceus), Yellowrumped Warbler (Dendroica coronata), Brownheaded Cowbird (Molothrus ater), and Northern Fulmar (Fulmarus glacialis). No species is represented by as many as 1,000 spirit speci-

mens. The five species most numerous in collections are: Red-headed Quelea (Quelea erythrops), Village Weaver (Ploceus cucullatus), Common Bulbul (Pycnonotus barbatus), Vireo olivaceus, and Passer domesticus. Some species have been collected in large numbers for studies of skeletal variation (e.g. Passer domesticus, Johnston 1969, Johnston and Selander 1971; Passerculus sandwichensis, Rising, in progress; Eremophila alpestris, Niles 1973). Others are received in large numbers by museums because of TV-tower kills (e.g. Seiurus aurocapillus, Vireo olivaceus, Dendroica coronata).

Management of Anatomical Collections

The inventories prepared by curators for this project will undoubtedly prove useful to them in reviewing the adequacy of their collections with respect to their particular goals and in judging the strengths and weaknesses of their collections in relation to regional and worldwide resources. Focusing attention on anatomical collections will, we hope, lead to improvements in their care and management. We also

hope that the deficiencies exposed by the composite inventory will provide a stimulus for the collecting of new material.

The publication of synoptic inventories will certainly stimulate exchanges among museums and provide more even coverage of material in various parts of the world. Arranging exchanges can be very time-consuming, but the inventories can be used to maximize the benefits of this work. It is far more useful for a curator of a North American museum, for example, to add a representative of a genus not found in any other North American collection than simply to add one new to his or her museum.

The inventories will allow curators of large collections that traditionally receive the major burden of loan requests to suggest additional sources to borrowers and allow a more equitable distribution of loans. This will clearly benefit the borrower and the large museum. Also, the small collection will thereby become more useful to the research community, which may be an important criterion for its continuing support.

Table 4. Numbers of species represented by various amounts of anatomical material.

Numbers of specimens	Preparation	
	Skeletons	Spirit specimens
0	2,706	2,957
1	919	1,027
2–5	1,757	1,949
6-10	1,026	1,086
11-25	1,216	1,128
26-50	614	501
51-100	364	237
101-200	214	89
>200	189	31

Finally, we hope that presentation of these composite inventories, incomplete as they are, will stimulate those in charge of unreported collections to submit their inventories to one of us for inclusion in a future printing.

RESEARCH

Undoubtedly, the inventories will foster anatomical research by facilitating the finding of specimens and the design of feasible research projects and by encouraging the collecting of new material. They clearly demonstrate that, while a few species are represented by large numbers, most are represented by few specimens or are lacking. This prompts us to ask whether or not we need large series of anatomical specimens (>100 per species), and whether or not existing collections meet the research needs of the present and immediate future.

The answer to the first question is "yes" for the following reasons.

- 1. Analyses of infraspecific variation in the avian skeleton are rare for lack of large samples of most species. Series of the same age, sex, season, physiological state, or geographical origin may be required. Such series may be impossible to assemble, even from large numbers of skeletons or spirit specimens. It is not reasonable to expect museums always to have the necessary specimens on hand, but they should have enough to indicate the potential of a proposed project.
- 2. Skeletal specimens are often poorly cleaned, incomplete, or damaged; simple totals do not reflect the number of *useful* specimens. Furthermore, skeletons are either articulated or disarticulated. Paleontologists, archaeologists,

and those analyzing hawk and owl pellets need disarticulated, well-cleaned specimens; systematists and functional anatomists often need articulated skeletons as well. Spirit specimens are sometimes poorly fixed or stored, and many were in substandard condition before they were fixed and are thus too hard, soft, or deteriorated for proper dissection. Difficult dissections may have to be done repeatedly to establish an anatomical relationship and to reveal a range of variation.

- 3. Skeletal specimens are relatively durable, but delicate ones may be broken with use, and small bones can be lost in packing and unpacking. Some spirit specimens are kept more or less intact as distributional records or documentation for published statements, but in general they achieve usefulness only in proportion to the degree to which they are dissected. Study of one anatomical system may ruin that specimen for other studies. Apart from such legitimate destruction, Burton (1980) has emphasized the hazard of loss of spirit specimens from drying. Thus, we see that both skeletons and spirit specimens should continue to be collected as replacements, even if augmentation of the collection is not an objective.
- 4. Several circumstances suggest a need to develop strong collections throughout the world. The collections useful for broad systematic research are mostly concentrated in North America and Europe. Laws, designed to protect populations of birds from over-exploitation by commercial trade, have inadvertently imposed burdens on museums by requiring permits or excessive documentation for routine international loans. Specimens are lost or damaged by postal and other systems with increasing frequency. Some museums prohibit loan of specimens represented by only one or a few individuals in their collections, and their curators have a responsibility to maintain collections for resident scientists and visitors. All of these facts point to the need for a higher degree of regional independence in satisfying the need for specimens.

Do existing collections meet the needs for present and future research? The answer is "only in part" for the following reasons.

1. The emphasis of systematic studies based on comparative anatomy in recent decades has changed from broad surveys of a few species or genera per family to detailed comparisons of many species and genera within families or orders. Many of the "characters" such as palatal types, leg muscle formulae, and toe arrangements used by earlier systematists are not necessarily homologous throughout birds. Furthermore, the states of such characters are less diagnostic of orders and families than was previously thought. It is important to survey as many species and genera as possible in any higher taxon to determine the variation and evolutionary trends in such features. Some orders and families that need further study are well represented in anatomical collections (e.g. Procellariiformes, Podicipediformes, Pelecaniformes, Anseriformes, Gruiformes, Charadriiformes, Tyrannidae, and many oscine families). Reference to Table 3, however, will show that other groups are not well enough represented in spirit or skeletal collections to permit extensively comparative studies in systematics, functional morphology and adaptation, ecomorphology, and other fields.

Stresemann (1959) thought that studies based on anatomical evidence have solved relatively few phylogenetic problems and that they are usually incapable of doing so. We think, however, that anatomical studies sufficiently comparative to support phylogenetic arguments are only beginning to be made and that comparative anatomy will become increasingly important in the elucidation of avian phylogeny.

2. Limitations of museum collections for studies on infraspecific variation, or even for pilot projects on such studies, have already been mentioned.

Conclusions

For broadly comparative studies or analysis of variation within species, the world's anatomical collections are often inadequate. Further selective collecting is needed on a broad scale. The forthcoming composite inventories are intended to maximize the efficiency of this endeavor. In the course of collecting new specimens it is essential to keep in mind that full data with each skeleton and spirit specimen are as important as they are with a skin. Field collectors, if not thoroughly familiar with the scientific uses of specimens, should become acquainted with the principles and practices presented in such papers as Miller (1940), Van Tyne (1952), Parkes (1963), Zusi (1969), and Burton (1980). We also remind collectors and curators that, when they obtain a rare or little known species as a fresh specimen, it may make a more significant contribution to knowledge as a spirit specimen or skeleton (and partial skin) than as a traditional skin.

We must emphasize that loss of habitat, declining avian populations, restrictions on collecting, and political hostilities are all obstacles to the development of collections. It is vitally important that ornithologists in all parts of the world build strong anatomical collections of their local avifaunas and of other avifaunas readily accessible to them, before the habitats and birds are gone. Otherwise, many ornithological questions of great significance will remain unanswerable for lack of material.

ACKNOWLEDGMENTS

We extend special thanks to all of the individuals who sent us inventories of the collections in their care. Others who helped us obtain inventories through correspondence or personal contacts were Walter Bock, Joe Marshall, Peter Morgan, Kenneth Parkes, and Lester Short. We are indebted to Christopher Wood for inventorying a major skeleton collection that would otherwise not be included. The University of Oklahoma has generously provided the computer services that make this project feasible. Mary Clench read the manuscript and made some valuable suggestions.
